Water Efficiency Handbook

Identifying opportunities to
increase water use efficiency in
industry, buildings, and agriculture
in the Arab Countries

Arab Forum for Environment and Development (AFED) is a not-for-profit organization, which brings the business community together with experts, civil society and media, to promote prudent environmental policies and programmes across the Arab region.

One of the main goals of AFED is propagating environmental awareness by means of supporting the role of environmental education and information and of non-governmental organizations active in the field of environment.

The main product of AFED is a periodic expert report on Arab environment, tracking developments and proposing policy measures. Other initiatives include a regional Corporate Environmental Responsibility (CER) program, capacity building for Arab civil society organizations, public awareness and environmental education.

AFED mission is to advance prudent environmental policies and action in the Arab countries based on science and awareness.

WATER EFFICIENCY HANDBOOK

This handbook is intended for use as a water use efficiency guide for industrial, residential, and agricultural water users across the Arab region.

Prepared for AFED by:
Dr. Murat Mirata and Dr. Tareq Emtairah

This first edition has been produced in cooperation with ACWA POWER, an AFED corporate member and the largest regional developer, owner and operator of independent water and power plants.

FOREWORD

Water in the Arab world is a precious and limited resource. The well-being of the region's populations and their prosperity are linked tightly to water availability and quality. In a region known for its arid climate and sparse rainfall, prudent water use is everyone's business. There are a number of strategies to achieve water security in a sustainable manner, but none is more significant than improving water efficiency.

Despite increased stress on water resources, many water users and managers are still unaware of practical, cost-effective water efficiency improvements they can make. Strategies or plans for water efficiency are largely lacking, both in the public and private sectors.

This handbook was developed to assist water users identify and prioritize cost-effective water efficiency opportunities. It targets water use in residential and commercial buildings, industrial plants, and agricultural farms. The handbook offers practical and proven methods to cut water consumption, and water costs, without sacrificing production, reliability, or comfort. By making this handbook available, water consumers at homes and water managers at institutional buildings, industrial sites and farms will be better informed about water efficiency retrofit opportunities, and will, therefore, be better prepared to develop a plan to take advantage of water savings.

Too often, projects to improve water efficiency do not get approval because of the initial capital expenditures required for retrofits, despite the fact that

up-front capital costs for financing water efficiency measures are usually recouped quickly through water savings. In fact, the return on investment in many cases is economically profitable, as demonstrated by the case studies in this handbook. In the long-run, the cost of inaction to the economy will be manifested by poor public health outcomes, lower resource productivity and pollution, to name just a few, which will far exceed the investments needed to increase water efficiency.

Making a transition to a water-efficient economy should no longer be viewed as a hard-to-reach, lofty goal. The barriers to a water-efficient economy are not technological or financial. To be sure, innovations and financing structures are indispensable to a water efficiency plan. The main impediment seems to relate to perceived attitudes. What is needed, therefore, is a firm belief in the capacity of every household and every organization to change how they consume water and take small steps to become water-efficient. This handbook expounds on the behavioral changes and practices that can be adopted.

The Arab Forum for Environment and Development (AFED) launched a preview edition of this handbook, together with its flagship report *Water: Sustainable Management of a Scarce Resource*, at AFED's Annual Conference in November 2010 in Beirut. Since then, the handbook was put into application, and comments were collected from users. This included a Water Efficiency Workshop organized by AFED in cooperation with ACWA Power in Riyadh in May 2011, using the handbook as guide, followed by a series of workshops and applications in other countries. This revised edition has been based on the feedback collected. Many sections were added, especially demonstrative case studies and guidelines for water audits, to make the handbook more complete as a tool for action.

We hope that this handbook will make a contribution to water efficiency in the Arab world, while improving the performance of its economies and institutions. Our ultimate goal is nothing short of fostering a new ethic of care and responsibility for water. Our health depends on it. Our economy depends on it. Our future depends on it. And it is the right thing to do.

November 2014

Najib Saab
Secretary General
Arab Forum for Environment and Development (AFED)

Another important dimension to water efficiency is the emphasis on closing the water cycle through recycle and reuse. For example, water discharged from one activity can be reused for the same or a similar activity. In other cases, water may not be fit to be reused in the same activity but it can be reused for another one that can tolerate lower quality water, after applying some treatment if necessary. In such cases, reuse and recycling improve water efficiency at a system level. Collectively, all these steps fall under the definition of water efficiency, as their purpose is to obtain the desired result or level of service with the least necessary water.

RELATED CONCEPTS

WATER PRODUCTIVITY

Water productivity is another useful measure of the amount of water used to generate an amount (or value) of product. It is typically used in assessing improvements in agricultural water productivity (water productivity in crop, livestock, and aquaculture production). However, the term is increasingly being used to measure water productivity in industrial output. For instance, we speak of the amount of water used per tons of product in comparing industrial water productivity across companies or countries. For additional information on this concept see The Stockholm Environmental Institute: www.sei.se

WATER FOOTPRINT

The water footprint is an indicator of water use that incorporates a life cycle perspective in the accounting of water use by a consumer or a producer. The water footprint of an individual, community, or business is defined as the total volume of freshwater that is used to produce the goods and services consumed by the individual or community or produced by the business. For businesses, the water footprint is useful when a company wants to consider not only water use in its operations but also in the company's supply-chain. This perspective can be very helpful in assessing water risk for businesses. For additional information on this concept see The Water Footprint Network: www.waterfootprint.org

ADOPTING A SYSTEMATIC APPROACH

There are many options and ways to improve water efficiency in commercial and industrial facilities. However, unorganized, ad-hoc approaches can lead to sub-optimal results. Therefore, a systematic approach is necessary in order to ensure the success of the water efficiency initiative and to achieve maximum return on investments.

The systematic approach we present in this handbook is modeled after Deming’s continual improvement cycle of plan, do, check, and act. Some of the details in the various stages were remodeled to fit regional conditions. **Figure 1.2** chart outlines the main steps for initiating and executing a water efficiency program.

FIGURE 1.2: Main steps of a systemic water efficiency programme

STEP 1

SITE REVIEW AND PLANNING

The main purpose of the site review and planning is to develop a base-line understanding of water use and to draft a plan for program implementation. The findings from this stage often serve as a roadmap for subsequent stages, allowing, for example, effective communication of benefits and costs of water efficiency programs in the organization or facility, which are necessary to secure the essential support and commitment of top management and employees. Activities that are included in the site review vary depending on the size and complexity of the site and available resources. In the following we present generic activities for the initial review, while recognizing that the resources invested into these activities must be considered in light of the size and type of facility.

DATA INVENTORY

One of the key objectives of the site review is to develop an understanding of quantities of water use and wastewater generation at the facility and activity levels along with their associated costs. A good starting point here involves reviewing existing data. While this seems straight forward, most facilities usually lack a comprehensive accounting of their water use and may not have the necessary data readily available. Significant information gaps can commonly be encountered during this stage and this can lead to frustration. Following checklist can be useful for compiling necessary information.

CHECKLIST

INFORMATION SOURCES FOR SITE REVIEW

- Process flow diagrams
- Site plans
- Direct readings from meters
- Water supply fees
- Water abstraction fees
- Energy and maintenance costs of pumping equipment
- Energy, chemicals, maintenance, and personnel costs for water and wastewater treatment units
- Equipment specifications
- Personnel familiar with daily operations such as operators and maintenance supervisors and staff

SITE SURVEY

Following data inventory, the next step is to conduct a physical survey of the facility in order to confirm previously gathered data and fill in the gaps. This entails a walk-through of the facility and interactions with relevant personnel. The site survey can also help reveal immediate water saving opportunities e.g. linked to leak detection and malfunctions. The following is a checklist of issues to consider during a site survey.³

CHECKLIST

A SITE SURVEY

- Check how water is supplied to the site, e.g. mains, tankers, and/or borehole. Record volumes and flow rates
- On-site water storage (if any). Record storage capacity
- On-site treatment (if any). Record treatment capacity
- Develop a list of all equipment that uses water, including process equipment, cooling towers, boilers, membranes, rinsing tanks, kitchen equipment, toilets, and showerheads, among others
- Check surveyed water-using equipment against your inventory data
- Compare floor plans, plumbing drawings, and schematics with actual conditions on site. Note discrepancies
- Calibrate all existing water meters to ensure accuracy
- Measure or estimate water use at the activity/process level including hours of operation/use, input water, lost water, in-product water and effluents
- Interact with staff, who are familiar with each water-use process by asking for suggestions for improvement.

SITE REVIEW REPORT AND ACTION PLAN

Upon completion of data inventory and site survey, it is time to collate the data into a baseline report. This report should provide a sufficient understanding of the water use in the facility and associated costs. Existing data and the site survey may not provide all the necessary information to develop an accurate water balance for the facility including a breakdown of water use by activity. This should be seen as a finding of the review process and necessary actions to fill the data gaps should be included in the plan. Support sheets that are available at the end of this chapter - and that focus on areas such as data recording, site questionnaires, alternative monitoring and measurement techniques, total cost accounting, visual presentation of data, and water quality assessment - can provide useful input for the planning phase.

Typically, a good baseline report should include the following:

- Description of the facility, number of staff, production volumes or users (for a building), process flow diagrams for industrial facilities and functional maps for buildings.
- A water flowchart that depicts the flow of water from the facility entry point to the point of discharge, including any reuse and recycle flows (see **Support Sheet D** for visual representation of data).
- Water use figures (total facility as well as a breakdown by operating areas or processes) and temporal variations (see **Support Sheet A** for filling gaps in data).
- Qualitative aspects of water flow in various areas (tap water, treated, greywater).
- Total cost accounting of water use in the facility (see **Support Sheet B** on how to calculate total costs).
- Summary of high volume/high cost water use activities or processes.
- Any additional water use observations revealed by the site survey, operations, or maintenance staff.

Additionally, an action plan for harvesting water efficiency improvements should be developed. Ideally, this plan should cover the following:

- Additional monitoring needs and time frames
- Preliminary efficiency targets (S.M.A.R.T targets)
- Key Performance Indicators (KPIs)
- Allocation of responsibilities
- Time frame and milestones
- Resource requirements.

IT IS IMPORTANT THAT THE TARGETS SET ARE S.M.A.R.T.

- Simple
- Measurable
- Achievable
- Recordable
- Timed

STEP 2

SECURE COMMITTEMENT & ENGAGEMENT

Achieving water efficiency requires a collective effort and demands support from within the organization. Top management, building owners, functional managers, and employees are particularly important parties.

Particularly in industrial facilities, getting **Top management** to have a good understanding of the objectives of water efficiency programs is key to securing high-level commitment. Top management should demonstrate support for the implementation plan by explicitly communicating its commitment to the program - by issuing a water productivity policy or including water use among the key performance indicators - and assigning direct responsibilities for the implementation of the plan.

Water efficiency work may have implications on other functions - production, maintenance, research and development (R&D), purchasing, and even marketing - and will demand their cooperation. Thus, it is also important to inform and engage **line managers** in water productivity work.

Finally, **employees and maintainece staff** are a crucial group whose involvement in the program is crucial. For one, employees will be counted on to incorporate and implement water efficiency measures in their daily routines. Equally important, however, is the fact that employees often act as an important source of useful ideas for efficiency gains. Therefore, starting from the early stages of conception, employees should be tightly involved in the program. Incentive schemes that reward employees for their contributions to water-saving measures are often highly effective in keeping their engagement level high.

STEP 3

IDENTIFY IMPROVEMENT OPTIONS

In order to make a healthy identification of improvement potentials, it would be necessary to have a representative understanding of water use related aspects on the site, and therefore generation or collection of additional data could be needed. Once the quantitative and qualitative aspects of water use in the organization are identified, the focus should be turned into efficiency improvements. The following generic approaches are usually helpful for identifying and ranking improvement options.

WASTE MINIMIZATION HIERARCHY

The hierarchy in **Figure 1.3** gives preference to preventative measures and offers useful guidance for prioritizing improvement options based on their nature.

In accordance with this hierarchy, the questions in the following check list (**Figure 1.4**) should be addressed in sequence while identifying opportunities for efficiency gains. Whenever there is a positive answer, the associated alternative should be investigated for implementation before moving on to the next question.

FIGURE 1.3: Hierarchy of preferred efficiency approaches

EFFECT ON LONG-TERM RISKS

In some cases identified improvements can be highly important for avoiding future risks - linked to, for example, anticipated regulations or conflicts with business partners or customers. These are important to take into consideration and can tilt the decision in their favor, particularly if their benefits can be expressed in monetary terms.

INTERNAL COMPETENCIES

The implementation of efficiency improvement projects adds to the learning capabilities of organizations. These projects provide opportunities for employees to acquire new competencies and develop new skills. In this sense, disruption to work flow should be welcomed as an avenue for professional development and employee retention.

IMPLEMENTATION

Based on the findings of the feasibility assessments, identified options should be placed in one of the categories listed in [Figure 1.5](#).

FIGURE 1.5: Categorization of improvement opportunities

STEP 5

MONITOR AND IMPORVE

Once efficiency measures are implemented, these should be closely monitored in order to assess whether the planned performance targets are met. If the observed performance is below target, reasons of under performance should be investigated and corrective measures should be identified and implemented. If necessary, monitoring, reasoning and corrective action cycle should be continued until the desired performance level is reached.

It is important to point out that water efficiency programs should not be treated as a one-time product or event. Rather efficiency should become an integral part of the organizational culture. After the first set of measures are implemented and fine-tuned, the program should move to its next stage by starting with a new review and planning step and continuing subsequent steps. Cultivating and nurturing this mindset in operations takes time. Communicating the results of the first set of improvement measures can create a leverage to initiate the next set of measures, which will slowly and surely put the organization on the path to becoming a water efficient entity.

WIDER ADOPTION OF THE SYSTEMIC APPROACH

Although some individual companies, motivated by economic incentives, apply a systemic approach to water efficiency, a large-scale adoption usually needs to be stimulated. Some factors that have proven to be effective in stimulating water efficiency in Western countries include:

- Stricter effluent discharge standards
- Demands from clients and business partners
- Informational and educational programs by governments
- Mandated water efficiency audits for facility and operational permits.

SUPPORT SHEET A

DATA COMPILATION

It is of utmost importance that the data is collected in a systemic way. Following provide examples of templates that can be used for compiling relevant information that are needed in improvement programs.

Whereas manual collection and handling of data is common practice and often provides sufficient results, there is an increasing trend towards automated, electronic data logging. Particularly suited for larger and more complex sites, such data logging approaches offer a number of benefits in terms of providing timely monitoring and detailed analyses.

EFFLUENTS

Average total wastewater discharge from the site (m³/month): _____

Fees for wastewater discharge ([unit]/m³): _____

Details of effluents

Discharge Point	Amount (m ³ /month)	Processes connected to this discharge point	Main constituents of effluents	Applied treatment (If any)	Cost of treatment ([unit]/m ³)
1					
2					
3					
4					
...					

Data Form for Institutional and commercial Buildings

General:

Name of the facility: _____

Location of the facility: _____

Contact name and details: _____

Primary function of the building Hotel Hospital Shopping centre Office
 School University Place of worship Other

Average number of users of the building per month: _____

No of hours the building is used per day: _____

Number of days the building is used per year: _____

Total Floor space in the building (m²): _____

Total land area belonging to the building (m²): _____

Footprint of building (m²): _____

Description of past or on-going water efficiency work on the site (e.g. water efficient fixtures, recycling or reuse activities, etc.):

Description of the water monitoring infrastructure on site (e.g. water meters for different sections, building management systems, etc.):

Enclose copies of **plant layout** and **water system** diagrammes for the site

EFFLUENTS

Average total wastewater discharge from the site (m³/month): _____

Fees for wastewater discharge ([unit]/m³): _____

Details of effluents

Discharge Point	Amount (m ³ /month)	Activities connected to this discharge point	Main constituents of effluents	Applied treatment (If any)	Cost of treatment ([unit]/m ³)
1					
2					
3					
4					
...					

Please provide the details of wastewater discharge standards/permits that the site has to comply with

NET PRESENT VALUE (NPV)

Although RoI is a relatively simple and effective approach, it does not take into account potential future risks or time value of money – \$100 in your pocket today is worth more than \$100 in your pocket in one year time. The Net Present Value (NPV) concept is attentive to such factors and if used with a properly selected discount rate, may provide more healthy assessments. NPV can be calculated using the following formula:

Net Present Value (NPV)

$$NPV = \sum_{t=1}^T \frac{S_t}{(1+r)^t} - C_o$$

Where:

T = total number of years that are taken into account in calculations

t = a given year (between 1 and T)

S_t = Anticipated savings in year t (=benefits – costs in year t)

r = discount rate

C_o = Initial cost of investment

The higher the NPV value of an alternative is, the better it is regarded to perform financially. Although the calculation may seem complex and cumbersome, NPV values can be easily calculated using built-in functionalities in common computer programs like Microsoft Excel. It should be re-emphasised that using the right discount rate is of utmost importance in these calculations.

GOOD PRACTICE GUIDE FOR WATER INTENSIVE OPERATIONS

LEAK DETECTION

Identifying leaks and taking corrective measures for their elimination offers a good starting point for water efficiency in industry. Underground water tanks, heating and cooling systems, water distribution network, and water using fixtures and equipment are areas where leaks are common. While some leakage can be easily spotted, some others may be hidden – like those from underground tanks or piping system inside the walls. If there is continuous monitoring of water use on site, baseline consumption that is observed during times of no activity on site would provide a good indicator of the extent of overall leakage (see [Figure 2.2](#)).

FIGURE 2.2: Continuous base flow indicates leakage

Measuring the water level during a time where there is no extraction from the tank can help identify leakage from tanks. Moisture, mold growth, or irregularities on surfaces can, on the other hand, be clues of leakage from pipes within the walls.

HEATING AND COOLING

Providing heat to or removing heat from different processes is a common practice in industrial systems. Cooling needs are particularly important in the Arab region due to the soaring temperatures of the summer months. Heat exchange systems often use water as an energy carrier. The following measures can assist saving water used for heating or cooling purposes.

EQUIPMENT AND SPACE CLEANING

MECHANICAL PRE-CLEANING

In equipment and space cleaning, the amount of required water can be substantially reduced by removing as much of the substances as possible by mechanical means – such as brushes, scrapers, rubber wipes, or pucks (for pipes). While reducing the water consumption, in certain cases the use of mechanical cleaning methods can also allow for the recovery of products that would otherwise be washed away by cleaning water.

CLEANING IN PLACE (CIP)

A triggered self shut-off nozzle

CiP is a method used for cleaning the interior surfaces of pipes, vessels, process equipment, and associated fittings, without disassembly. It is particularly useful for industries requiring high levels of hygiene and therefore frequent cleaning – such as beverages, dairy, processed foods, cosmetics, and so on. In such systems, a sequence of acidic and basic solutions and rinsing water is passed through the equipment to be cleaned. Because it allows different number of re-circulations for different solution and rinsing batches, CiP consumes significantly less water compared to conventional once-through cleaning systems. In addition, CiP systems are faster, less labor intensive, and pose less chemical exposure risk to people. High-pressure, low-volume systems

These systems usually apply a pressurized stream of water, or an air-water mixture, flowing at a high velocity through a specially designed nozzle. Commonly applied for equipment and space cleaning, these systems can provide the same, or even better, cleaning effect by using as much as 50% less water.

USE OF TRIGGERED, SELF SHUT-OFF NOZZLES

In space and equipment cleaning using ordinary hoses, significant amounts of water can be lost as the “on-off” valve is often fitted on an outlet far away from the place of use. Fitting triggered self shut-off nozzles at the discharge ends of hoses offers effective and low-cost alternative for reducing water use.

USE OF STEAM OR HOT WATER

Similar to product rinsing, equipment and space cleaning can be assisted by the use of chemical detergents or higher temperature water. Again, the additional costs of chemicals and/or energy need to be weighed against the benefits of reduced water use.

KITCHENS

Kitchens in different settings are another high-water use area, particularly in commercial and institutional buildings, such as hotels, schools, restaurants, and shopping centres. Once again, with a combination of behavioral and technical changes, water use in the kitchens can be reduced considerably.

ELIMINATE USING RUNNING WATER FOR FOOD PREPARATION

Both in domestic and commercial kitchens vegetables and fruits need to be washed prior to being used in food preparation. Instead of washing under running water, using a water container can be equally effective. Additionally, avoid using running water for defrosting. This practice wastes large quantities of water. Instead, defrosting can be achieved by placing frozen food items in a refrigerator or in a room environment for a reasonable amount of time (beware of time to avoid food spoilage). Microwave ovens can also be used for defrosting.

USING A DISHWASHER

Whenever possible, dishes and utensils should be washed using dishwashing machines because they are far more water efficient than manual washing. For commercial applications, and also for households, preference should be given to machines that have higher water efficiency. Such dishwashers should be run once fully loaded, rather than at partial loads. It should be noted that modern domestic dishwashers that utilize high-pressure steam can easily handle a great majority of the dirt found on dishes and **DO NOT** require pre-rinsing.

MECHANICAL PRE-RINSE FOR MANUAL WASHING

Where manual washing is the only option, priority should be given to removing food residues from dishes by mechanical means, such as with the help of a used napkin or a brush, over using running water. If necessary, dishes could be soaked in a container to allow the residues to soften. Actual washing and rinsing should also be performed using batches of water placed in containers instead of running water.

TRIGGERED SPRAY NOZZLES

In commercial kitchens, pre-rinsing of the dishes is common in order to reduce water and chemical consumption in quick-cycle dishwashers. In such activities, use of high-pressure nozzles with a hand-held trigger can result in substantial water savings.

A tap with a triggered spray nozzle can save a lot of water in kitchens
Picture: Superb Lifestyle products

USE OF HOT WATER

Hot water is much more effective in removing food remains from dishes and therefore provides equal or better cleaning with much lower volumes than cold water. However, the energy costs of water heating need to be taken into consideration.

ICE MAKERS

Commonly found in restaurants and hotels, ice makers can use considerable amounts of water. Air cooled machines, which require only about 1.9 liters of water per kilogram of ice, should be preferred over water cooled machines, which may use as high as seven times more water.

SPACE CLEANING

Commercial kitchens need to be frequently cleaned for hygienic purposes. A number of measures can be adopted to reduce water use. Sectioning the areas according to cleaning needs, utilizing mechanical cleaning to the extent possible, and using high-pressure, low-volume systems can collectively help reduce water consumption for space cleaning.

LANDSCAPING

Water use for landscaping can consume considerable amounts of water and usually holds a good potential for efficiency gains. Three main approaches are effective in reducing the amount of water used in landscaping:

SELECTING THE RIGHT PLANT SPECIES

Plant species hold the most important promise for reducing water consumption. Unfortunately, exotic plant species that are not native to the local environment are commonly used in gardens, which demand excessive quantities of water and additional maintenance. In semi-arid areas, characteristic of most MENA countries, drought-tolerant varieties should be the preferred option. Drought-tolerant plants are an essential part of water efficient landscapes. They are adapted to water-scarce environments and therefore require minimal supplemental irrigation. They also require less maintenance than their water-needy counterparts.

OPTIMIZATION OF IRRIGATION SYSTEMS

Irrigation can be performed by hand or through a dedicated installation. When choosing an irrigation set-up, below ground irrigation systems should be prioritized over above ground systems, thus minimizing evaporation losses. In addition, synchronizing irrigation to changes in soil moisture content is more efficient than relying on pre-set frequencies. When managed

WATER CONSERVING LANDSCAPES PROJECT IN JORDAN

- The Center for the Study of the Built Environment (CSBE) project on water conserving landscapes is concerned with the development of aesthetically pleasing landscapes that also conserve the use of water. These goals are achieved through a variety of means, which include using native and drought-tolerant vegetation, making maximum use of rainfall runoff, and incorporating hard-covered ground surfaces (consisting of materials such as pebbles, stones, bricks, and concrete) in landscape designs, rather than relying exclusively on surfaces covered with vegetation.
- The project generates informative educational leaflets and manuals in both Arabic and English on water conserving landscapes, featuring a list of drought-tolerant plants adapted to the region. Available for free at: <http://www.csbe.org>

A hand-held soil moisture meter

properly, an automatic irrigation controller can pay for itself in reduced water usage, cost, and labour. By using a simple device to monitor the soil moisture content continuously, significant efficiencies can be gained.

Irrigation equipment needs to be properly maintained on a regular basis, including making adjustments to the sprinkler heads or drip nozzles as needed.

USE OF HARVESTED RAINWATER AND GREYWATER

Landscape irrigation is often well-suited to using alternative sources of water, such as greywater, harvested rainwater, or even treated wastewater that can be sourced from municipal water works in some contexts. **Figure 3.4** depicts a water harvesting system.

HEATING AND COOLING

In commercial and institutional buildings with large floor areas, centralised heating, ventilation, and air conditioning (HVAC) systems are frequently used. These systems are highly similar to heating and cooling systems described in **Chapter 2** (Water efficiency in industrial facilities), and can benefit from the same efficiency measures.

FIGURE 3.4: An active water harvesting system²

EARLY DESIGN MEASURES

Water efficiency should be integrated early on in the design and construction phase of buildings. The feasibility of certain efficiency measures can be enhanced by re-considering certain design features related to the water distribution network, water storage tanks, and other water supporting systems. In the following are examples of three systems.

CHECKLIST

WATER EFFICIENCY MEASURES FOR HVAC SYSTEMS

- Adjusting the heating and cooling loads to actual demand
- Replacing once-through systems with re-circulating systems
- Reducing bleeding through close monitoring of impurities and use of appropriate chemicals
- Properly maintaining the system components
- Reducing drift and splash losses from cooling towers
- Reducing excessive overflow by properly adjusting the level of float valves in cooling tower storage tanks
- Consider use of alternative water sources.

WATER STORAGE TANKS

Commercial and institutional buildings are usually equipped with water storage tanks, which serve two functions. It is an available, if temporary, source of water when regular supply from the water distribution network is interrupted. Stored water can also be used for fire-fighting purposes. For maintenance reasons, these tanks need to be emptied at certain intervals and their contents are usually drained.

To save water, the water storage tank should be designed with two independent cells, each occupying a 50% capacity of the total tank volume. With a two-compartment tank, water from one cell can be circulated to the other cell during maintenance, precluding the need to drain the entire water content of the tank. Therefore, the two water cells should be connected to each other, allowing water circulation and ensuring water quality maintenance. Water cells should also be designed to allow them to be emptied independently (for washing or maintenance purposes).

WATER DISTRIBUTION NETWORKS

CHECKLIST

INDEPENDENT WATER SECTORS IN A COMMERCIAL BUILDING

- One sector per floor
- One sector for the common areas (corridors, technical areas, others)
- One sector for the HVAC system
- One sector for the irrigation system
- One sector for ornamental fountains, when available

Another approach that can result in water efficiency gains in commercial and institutional buildings is to design the internal water distribution network with clearly independent sectors, defined by both the area of the building and the type of water consumption. In the following box are examples of independent water sectors that can be considered for commercial buildings. Each sector should be equipped with a water flow meter measuring the specific water consumption in that sector independent of others.

Independent monitoring of the sectors helps gain an understanding of water use patterns in different sectors as well as identify and isolate possible water leaks in the building.

INFRASTRUCTURE FOR WATER RE-USE

As mentioned earlier, greywater produced by certain uses in buildings – such as showers, wash basins, and laundry rooms – can be of suited for use in toilet systems or in landscaping. To facilitate the use of greywater, it is key to include in the early design phase a system for collecting, treating, and storing treated greywater. This system may include a separate drainage network, an on-site simple treatment unit – e.g. using sand filters or ultra-filtration –, a storage tank, and a dedicated distribution network.

Similarly with rainwater harvesting, a collection, treatment and storage and distribution infrastructure is needed.

RAINWATER HARVESTING

Rainwater collected primarily from roofs or other suitable paved areas – such as parking lots – can reach considerable amounts and can be used for a variety of purposes, such as:

- Landscape irrigation;
- Toilet flushing;
- Laundry;
- General cleaning;
- Cooling and heating;
- Hygienic use and drinking.

A rainwater harvesting and re-use system includes the following components.

CATCHMENT AREA: An impermeable surface, like roof or parking lot, is needed to capture the rainfall.

CONVEYANCE SYSTEM: Appropriate piping and drainage needs to be in place in order to transfer the captured rainwater first to the treatment units and then to the storage tank.

FILTRATION/TREATMENT: Captured rainwater often needs to be treated. The extent of treatment needed depends both on the characteristics of the catchment area and the intended use of the collected water. Usually water collected from roofs has lower amounts of pollutants than those collected from pavements or parking lots and therefore require less treatment. Generally, the first part of the collected runoff is flushed away, as it tends to be rich in impurities. The water is then passed through a filtration unit to retain organic and other impurities. While a coarse filtration – such as one that can be achieved with a simple grate filter or sand filter – may be sufficient for relatively clean harvests, finer filtration – such as micro-filtration – may be needed for others – particularly if the intended use for the water requires higher quality.

STORAGE: The filtered water is then placed into a storage tank. The dimensioning of the tank is an important consideration, and requires an estimation of the amount that can be harvested. The amount of rainwater that can be harvested on a specific site can be calculated using the following formula:

$$VRain = \frac{AxPx0.8}{1000}$$

where:

VRain = Volume of rainwater (in m³/year)

A = Collection area (m²)

P = Average annual precipitation³ (in mm)

0.8 = Collection factor to account for filtering losses and small rainfall that does not generate runoff.

Storage tanks need to be fitted with an overflow system. Moreover, if the tank will need to be topped up with water from the main, a backflow prevention device will need to be fitted.

DELIVERY SYSTEM: Pumps, valves and pipes may be needed to transfer the collected rainwater to the point of use. Depending on the design of the system, if a pump is needed to transfer the collected water to the point of use, this can be placed inside the tank. If the rainwater needs to meet higher hygienic requirements or will be used for drinking, additional treatment units, such as granulated activated carbon filtration and UV disinfection may need to be integrated to the distribution system.

An alternative design for a simple rainwater harvesting system is depicted in **Figure 3.5**.

CARE NEEDED: The storage tanks of rainwater harvesting systems need to be cleaned in frequent intervals – the frequency is dependent on the tank design and level of filtration.

Particularly in warmer climates, the storage tanks can easily turn into breeding grounds for mosquitos and other nuisance insects. In order to prevent this from happening, all non-frequently used orifices need to be properly closed and sealed. Orifices that are commonly used – like input and overflow pipes, on the other hand need to be covered with a mesh.

CHAPTER 4 WATER EFFICIENCY IN AGRICULTURE

WATER EFFICIENCY OF IRRIGATION CAN BE IMPROVED BY MAKING THE RIGHT DECISIONS REGARDING:

- Crop selection
- Irrigation scheduling
- Irrigation methods
- Source of water

Globally, agriculture is the largest user of water¹ and also uses 85% of the water withdrawn in the MENA region. Additionally, water use in agriculture is often highly inefficient with only a fraction of the water diverted for agriculture effectively used for plant growth, with the rest drained or lost via evapotranspiration.

With population growth and rising affluence, the need for food and thus agricultural water for irrigation is increasing. At the same time the quantity of water with a sufficient quality is declining. There is also an increasing demand to shift more of the water used in agriculture to higher-value urban and industrial uses. Thus, producing more with less is the only option.

Water efficiency in agriculture has been extensively researched for many years. Universally applicable solutions are however difficult to come by, particularly due to different contexts and high specificity of agricultural practices. But efficiency gains are often possible through suitable crop selection, proper irrigation scheduling, effective irrigation techniques, and using alternative sources of water for irrigation. It should be noted that increasing water efficiency often provides benefits that go far beyond reduced water use.

IMPROVING WATER EFFICIENCY IN IRRIGATION

IMPROVING IRRIGATION PRACTICES CAN:

- Reduce water and pumping costs
- Reduce costs for fertilizers and other agricultural chemicals
- Maintain a higher soil quality
- Increase crop yields – by as much as 100%

Irrigation is necessary when plants cannot satisfy all their water needs through natural precipitation – this practice is also called deficit irrigation. Therefore, an ideal irrigation effort aims to cover the deficit between a crop’s optimal water needs and what it can take up through natural means. Because arid, semi-arid, and desert climatic conditions prevail in the Arab region, irrigation is indispensable.

Climatic conditions, soil type and structure, plant type, and the irrigation techniques applied are among the main factors that influence the efficiency and effectiveness of irrigation practices. For a given location and climatic and soil conditions, the efficiency of water irrigation practices can be improved by making the right decisions regarding:

- Crop type
- Irrigation scheduling
- Irrigation method
- Soil enhancement measures
- Source of water

CROP WATER NEEDS

Crops differ both in terms of their daily water needs and the duration of their total growing period. Consequently, crop type is a chief factor influencing irrigation water needs. Crops with high daily needs and a long total growing season require much more water than those with relatively lower daily needs and shorter growing seasons. Therefore, a key step towards reducing irrigation water needs is selecting those crop varieties that have a lower water demand but that still provide sufficient added value.

In **Tables 4.1, 4.2, and 4.3**, values of typical water needs, average length of growing season, and the total water demand for different crops are given.

TABLE 4.3: Approximate values of seasonal crop water needs⁴

Crop	Crop water need (mm/total growing period)
Alfalfa	800 - 1600
Banana	1200 - 2200
Barley/Oats/Wheat	450 - 650
Bean	300 - 500
Cabbage	350 - 500
Citrus	900 - 1200
Cotton	700 - 1300
Maize	500 - 800
Mellon	400 - 600
Onion	350 - 550
Peanut	500 - 700
Pea	350 - 500
Pepper	600 - 900
Potato	500 - 700
Rice (paddy)	450 - 700
Sorghum/Millet	450 - 650
Soybean	450 - 700
Sugarbeet	550 - 750
Sugarcane	1500 - 2500
Sunflower	600 - 1000
Tomato	400 - 800

IRRIGATION SCHEDULING

Irrigation scheduling helps eliminate or reduce instances where too little or too much water is applied to crops. Scheduling is performed by all growers in one way or another. However, proper irrigation scheduling involves fine-tuning the time and amount of water applied to crops based on the water content in the crop root zone, the amount of water consumed by the crop since it was last irrigated, and crop development stage. Direct measurement of soil moisture content is among the most useful methods for irrigation scheduling. The extent to which farmers can utilize advanced irrigation depends on their access to water and labor. The economics, and in particular the critical impact of water availability on the yield, also play a role on the uptake of advanced irrigation scheduling.

Crops need different amounts of water at different stages of their growth cycle. In addition, local climatic and soil conditions influence the availability of water to crops. It should be kept in mind that excessive water provision can also be counterproductive as crops cannot utilize excess water and may be stressed from reduced oxygen levels of saturated soil. This practice will also waste not only water but also energy and pumping costs. Consequently,

it is essential to plan for irrigation properly and match the amount of water provided to a crop's water needs – both for yield optimization and for water efficiency. With proper irrigation scheduling, soil reservoir is managed such that optimum amount of water is available when the plants need it. Good irrigation scheduling requires knowledge of:

- Crop water demand at different growth cycles
- Moisture content of the soil and soil water capacity
- Weather conditions.

During the early season planting stage, the water requirement is usually about 50% less than what is required at the mid-season stage, when the crop has fully developed and reached its peak water need. The late season demand, on the other hand, is as high as the peak demand for crops harvested fresh, and can be as much as 75% less for those plants harvested dry. It is essential for growers to be attentive to this irrigation schedule and for the irrigation system to be adaptable to such changing demands.

Although overall water needs of different crops can be approximated using the typical values given in **Table 4.1**, **4.2**, and **4.3** above, determination of these values at different growth stages is more complicated because water needs can show significant variations based on local climatic and soil conditions and crop variety. It is therefore important to consult competent authorities – e.g. Agricultural Ministries or local Irrigation Departments – to obtain relevant information.

Monitoring of soil moisture content provides a good assessment of the crop's water needs. A wide range of methods offering varying accuracy levels is available for monitoring soil moisture, each having its respective strengths and shortcomings. Some of the common methods are summarized in **Table 4.4**.

TABLE 4.4: Overview of approaches for monitoring soil moisture⁵

Method	Advantages	Disadvantages
Feel and appearance at different depths of the crop root zone	Very simple and requires no cost	Has low accuracy (but can be useful if visual guidance by competent authorities is provided)
Gravimetric methods	<ul style="list-style-type: none"> Inexpensive and accurate Works well for all soil types and moisture levels 	Takes a long time to obtain results
Gypsum blocks	<ul style="list-style-type: none"> Simple and inexpensive Accurate when the conditions are right 	<ul style="list-style-type: none"> Requires individual calibration Not accurate in very wet or saline soil Readings are affected by soil temperature and fertilizer content New blocks needed every year
Granular matrix sensors	<ul style="list-style-type: none"> More accurate Offers more stable calibration Possibility for automated plotting of readings over time 	More costly
Tensiometers	<ul style="list-style-type: none"> Reusable No need for calibration 	<ul style="list-style-type: none"> Does not work well in coarse sand and in some clay soils Fails to read at higher tensions of drier soils Requires regular maintenance
Capacitance or frequency domain sensors	<ul style="list-style-type: none"> Provides immediate readings Can be installed permanently or be used as mobile modules 	<ul style="list-style-type: none"> Salinity and soil texture affect readings Needs calibration prior to use Air pockets near probes or access tube walls give errors
Neutron probe	<ul style="list-style-type: none"> Provides very accurate data Quick and reliable if used by trained operators serving multiple farmers 	<ul style="list-style-type: none"> Requires calibration Has low level radiation safety issues Requires trained operator Costly

Soil capacity, which is the ability of the soil to hold water between irrigation or precipitation events, is another important factor. Determinants of soil capacity include soil depth, ratios of different soil particles making up the soil, soil porosity, and soil water tension.⁶ These factors influence the amount of water available to the plants. Because soil properties change at various depths, it is important to know the soil capacity throughout the plant root zone. It should also be noted that during irrigation, or precipitation, water only reaches a zone at a lower depth once the preceding zone has become fully saturated. Soil capacity surveys are usually difficult to perform by individual farmers, but can be performed by competent authorities and the information can be made available for different regions.

The prevailing **climatic** conditions, such as average ambient temperature, intensity of solar radiation, humidity, and wind-speed also affect both the moisture retained in the soil and the speed by which plants lose water through transpiration. The highest crop water needs are found in areas that are hot, sunny, dry, and windy. Thus, climatic conditions also need to be taken into consideration for proper irrigation scheduling.

Accurate monitoring of water used in irrigation is an essential part of irrigation scheduling and helps reach optimal performance, saving water while enhancing yields. Accurate readings can be obtained through different direct measurement methods available for pipes and closed conduits (propeller meters; orifice, venturi, or differential pressure meters; magnetic flux meters; ultrasonic meters) and for open channels (weirs and flumes; stage discharge rating tables; area/point velocity measurements; ultrasonic methods). Indirectly measuring irrigation water use can also provide sufficiently accurate approximations at lower costs. Common methods used include:

- Measurement of energy used by irrigation pumps
- End-pressure measurements in sprinkler irrigation
- Elevation differences in irrigation reservoirs or tanks
- Measurement of irrigation time and size of irrigation delivery system.

IRRIGATION METHODS

Once the quantitative and temporal characteristics of optimal water demand have been determined, a method that can make such water available in the most effective way should be selected. There are three main irrigation methods, namely:

- Surface (or gravity) irrigation
- Sprinkler irrigation
- Drip irrigation.

These methods, and their respective advantages and disadvantages are summarized.

SURFACE IRRIGATION

Surface irrigation involves the application of water by gravity flow to the surface of the field. Surface irrigation can have different forms. In basin irrigation, the whole field is flooded with water. Alternatively, furrow or border irrigation can be used where water can be fed into small channels or strips of land. Surface irrigation is the easiest and least costly method, but is usually highly inefficient – only less than 10% of the water is taken up by the plant. Unfortunately, this is also the widely most used method in the Arab region.

SPRINKLER IRRIGATION

Sprinkler irrigation systems imitate natural rainfall. Water is pumped through pipes and then sprayed onto the crops through rotating sprinkler heads. These systems are more efficient than surface irrigation, however,

they are more costly to install and operate because of the need for pressurized water. Conventional sprinkler systems spray the water into the air, losing considerable amounts to evaporation. Low energy precision application (LEPA) offers a more efficient alternative. In this system the water is delivered to the crops from drop tubes that extend from the sprinkler's arm. When applied together with appropriate water-saving farming techniques, LEPA can achieve efficiencies as high as 95%. Since this method operates at low pressure, it also saves as much as 20 to 50% in energy costs compared with conventional systems.

Different sprinkler irrigation systems – conventional (left) and low energy precision (right) systems

DRIP IRRIGATION

Drip irrigation delivers water through the use of pressurized pipes and drippers that run close to the plants and that can be placed on the soil surface or below ground. This method is highly efficient because only the immediate root zone of each plant is wetted. This system also allows precise application of water-soluble fertilizers and other agricultural chemicals. Drip irrigation is reported to help achieve yield gains of up to 100%, water savings of up to 40-80%, and associated fertilizer, pesticide, and labor savings over conventional irrigation systems⁷ Drip irrigation systems can have different levels of sophistication and costs. Drip irrigation systems that are operated by solar-driven pumps are a particularly promising alternative for the MENA region. **Figure 4.1** shows a layout of a drip irrigation system. The variations in soil moisture content usually achieved with different irrigation methods are depicted in **Figure 4.2**.

With the exception of Saudi Arabia and the United Arab Emirates (UAE), surface irrigation is predominantly used in more than 90% of irrigated agricultural land in the MENA region⁹

APPENDIX A: CASE STUDIES

- Case Study 5:** Efficient landscaping in a residential garden - Jordan

CASE STUDY 1

REDUCTION AND REUSE OF WATER IN A DAIRY FACILITY, SAUDI ARABIA

With daily production reaching 400,000 liters, this company is the largest ultra high temperature (UHT) recombined milk producer in Saudi Arabia. Everyday, the company purchases 2,020 m³ of water and discharges 1,420m³ of wastewater.

When it has realized the strategic importance of water, the company decided to systematically address water efficient use. A group's operations engineer, with extensive international resource productivity experience, was brought to the Jeddah site.

Water use was quickly assessed and the specific consumption was determined to be **4.26 liters of water for each liter of milk**. Through the engagement of employees a set of **SMART** targets was set up.

New water meter installed

In the next step, the company has installed water meters in the lines suspected to be large users.

Material for the case study is provided by Wafeer Initiative, see: www.wafeer.net

* Note that the water savings are restricted to the plant and do not cover the milk production itself, which is a water-intensive process in Saudi Arabia, as feed is often irrigated by non-renewable ground water.

“Once-through” cooling system was found to be a major source of water wastage. The existing system for the equipment with the largest cooling loads was transformed into a “re-circulating” system by retrofitting the necessary pipes, pumps, and cooling tower. Work is underway to install re-circulating cooling systems for other pieces of equipment.

CASE STUDY 2

INTERNAL AND EXTERNAL RECYCLING IN A PAPER PRODUCTION FACILITY, JEDDAH, SAUDI ARABIA

Running a water intensive process like paper production in Saudi Arabia, a water-scarce country, is a challenging task. The management of the paper production company was highly aware of this challenge and decided to meet it with strong commitment and continuous innovation. First, the company reached an agreement with the nearby municipal wastewater treatment plant to permit reuse of treated domestic wastewater in the company’s operations. This has already enabled significant water productivity gains. However, the innovations did not stop there.

When it started operations, the plant used 20 m³ of water for every ton of product. Convinced about the possibilities to reduce this ratio, the company’s management aggressively searched for options. With input from the general manager, trained as an environmental engineer, the company systematically screened all water inefficiencies in the plant and thoroughly assessed all effluent streams for their recycling potential. Based on these assessments, a treatment unit consisting of screens, drum filters,

Material for the case study is provided by Wafeer Initiative, see: www.wafeer.net

two dissolved-air floatation units, and gravity filters was installed to treat effluent streams. Treated effluents are now fed back into the process for reuse.

With this new arrangement, the company managed to reduce its specific water consumption from 20 to 8 m³/ton of product. This system has also allowed the recovery of fibers and boosted the plant's fiber conversion efficiency from 80 to 90%. With the introduction of additional steps to allow the internal recycling of water, the company was able to reduce its water consumption by 420,000 m³/year. The investment made was paid back in two years. This initiative is saving the company around US\$400,000 every year. Results of the company's water efficiency program are summarized in [Table 5.2](#).

TABLE 5.2: Summary results of the water efficiency program at a paper production facility

Water savings	420,000 m³/year
Financial savings	US\$400,000 /year
Approaches used	Internal and external recycling
Key success factors	Solid commitment from top management; systemic approach; effective monitoring; high technical capacity

CASE STUDY 3

SAVING WATER AND MONEY IN A FOOD PROCESSING FACILITY, EGYPT

Excessive water use at a food processing facility, a major producer of frozen potatoes and vegetables, was forcing the company to bear additional costs. Where the facility is located, there was an excess pressure on water resources and on the sewer network in the area. Moreover, the food plant's high rates of wastewater generation were having negative impacts on the surrounding environment. When the company realized the strategic importance of reducing water consumption, it decided to address the efficient use of water in the company's operations.

Potatoes processed by the company

Material for this case was provided by the Egypt National Cleaner Production Center (www.encpc.org), which is affiliated with the Ministry of Trade and Industry (MTI) in close cooperation with the United Nations Industrial Development Organization (UNIDO).

Originally, the company's average water consumption was about 5.1 m³/ton of product while the industry norm is averaging about 4 m³/ton. Process operations in the food facility were re-analyzed in order to identify opportunities for reducing water consumption. This analysis has prompted the company to implement projects to repair water leaks and to reuse water. Water leaks in the cooling towers area were repaired, leading to reduced water use by about 26,000 m³/year and cost savings on the order of US\$6,000 /year.

Water reuse projects were implemented throughout the plant at an investment cost of about US\$10,500, resulting in water savings of about 120,000 m³/year and US\$27,000 /year in cost savings. The payback period, after electricity and maintenance costs were factored in, was about 4.3 months.

As a result of implementing these water efficiency projects, the company's new water consumption average was about 3.04 m³/ton of product, which is below the world average standard for this industry. The outcomes of the company's water efficiency program are summarized in [Table 5.3](#).

TABLE 5.3: Summary results of the water efficiency program at a food processing facility

Water savings	146,000 m³/year
Financial savings	US\$33,000 /year
Approaches used	Reuse, leak repairs
Key success factors	Key success factors Top management support; effective monitoring; good practical training

CASE STUDY 4

GREYWATER RECYCLING AND REUSE IN A HOTEL BUILDING, DEAD SEA, JORDAN

Water is a scarce commodity in Jordan. During peak season, a Spa Hotel on the Dead Sea, Jordan, has to hire private water suppliers to fill the hotel's water tank up to ten times every day. The cost to the hotel business and the environment is considerable. Public water supply is available at a significantly lower price, but it comes nowhere near to satisfying the needs of this four-star hotel.

The Dead Sea Spa Hotel

Approximately 80 per cent of the wastewater generated daily by each hotel room at a wellness facility like the Dead Sea Spa Hotel takes the form of greywater. This water comes from baths, showers, and wash basins, and can be treated and reused. When the growing stream of tourists made it necessary to expand the hotel complex in 2008, it became more critical for the hotel owner to try new ways of managing water at the resort.

The hotel became a pilot operation and the first company in the Arab world to install a modern greywater recycling plant that allows greywater to be reused within a single building. With support from the Jordanian water authorities and technical

Material for this case study was kindly provided by the GTZ program in Jordan. The greywater system was supported by Pontos GmbH, a subsidiary of Hansgrohe AG. Contact information: Dieter. Rothenberger@gtz.de, Friederike. Sorg@gtz.de. For further information see www.developpp.de.

assistance from Deutsche Gesellschaft für Technische Zusammenarbeit (GTZ) GmbH on behalf of the German Federal Ministry for Economic Cooperation and Development (BMZ), a greywater capture and treatment system was installed in the hotel. A public-private partnership (PPP) was formed to ensure that hotel staff and Jordanian plumbing companies receive training in assembling the plant and carrying out maintenance work independently.

Greywater from the Dead Sea Spa Hotel is now being turned into high quality industrial service water that meets the hygiene requirements of the European Union (EU) Bathing Water Directive. The water is treated without chemical additives in an entirely mechanical-biological process and is subsequently used to flush toilets. A summary of the hotel's greywater recycling program is shown in **Table 5.4**.

Greywater recycling system

TABLE 5.4: Summary results of greywater recycling at a hotel

Water savings	17 % of total water consumption in the hotel
Financial savings	US\$80,000
Approaches used	High quality greywater treatment and reuse
Key success factors	Investment costs can be minimized if integrated in early planning
